

Ch-8 - Strings

- A string is a 1-D character array terminated by a null ('\\0') → This is null character.
- null character is used to denote string termination
- characters are stored in contiguous memory locations.

Initialization of strings

- Since string is an array of characters, it can be initialized as follows:

```
char S[] = { 'H', 'A', 'R', 'R', 'Y', '\\0' };
```

There is another shortcut for initializing strings.

```
char S[] = "HARRY";
```

⇒ In this case C adds a null character automatically

Strings in Memory

- A string is stored just like an array in the memory as shown below

H	A	R	R	Y	\\0
(82210)	(82211)	(82212)	(82213)	(82214)	(82215)

→ null character

Contiguous blocks in memory

Quiz: Create a string using " " & print its content using a loop.

Code: #include <stdio.h>

int main () {

char str[] = "Harry";

```
char *ptr = str;
while (*ptr != '\0') {
    printf("%c", *ptr);
    ptr++;
}
```

return 0;

Output
Harry

Code: #include <stdio.h>

int main () {

```
char *ptr = "Harry";
printf("%s", ptr);
return 0;
```

Output
Harry

strncpy: If source string is longer than target string, the overflow characters are discarded automatically. Date
`strncpy(target, source, target - len + 1);`
`target[target - len - 1] = '\0';`

Printing Strings

A string can be printed character by character using printf & %c.

But there is another convenient way to print strings in C:

`char st[] = "Harry";`
`printf("%s", st);` \Rightarrow prints the entire string

Taking string input from user

We can use %s with scanf to take string input from the user

`char st[50];`
`scanf("%s", st);`

scanf automatically adds the null character when the enter key is pressed.

Code: `#include <stdio.h>`
`int main() {`
 `char s[34];`
 `printf("Enter your name: ");`
 `scanf("%s", s);`
 `printf("Your name is %s", s);`
 `return 0;`
}

Output

Enter your name
Adwait

Your name is Adwait

Note:

1) The string should be short enough to fit into the array.

2) scanf cannot be used to input multi-word strings with spaces.

gets() & puts()

gets() is a function which can be used to receive a multi-word string.

char st[30];

gets(st); \Rightarrow The entered string is stored in st!

Multiple gets() calls will be needed for multiple strings

likewise, puts can be used to output a string

puts(st); \Rightarrow prints the string placed at the cursor on the next line

Declaring a string using pointers
we can declare strings using pointers

char *ptr = "Harry";

char*ptr & char ptr[] are same.

Date _____
Page _____

This tells the compiler to store the string in memory & assigned address is stored in a char pointer.

Note:

Once a string is defined using char str[] = "Harry", it cannot be initialized to something else.

2) A string defined using pointers can be re-initialized.

Cede: ~~#include <stdio.h>~~

```
char ptr[] = "Harry";
```

```
ptr = "Shubham";
```

```
printf("%s", ptr);
```

```
return 0;
```

string cannot be copied using library functions.
If source string is longer than target, the overflow
characters may occupy the memory space used
by other variables.

C provides a set of standard library
functions for string manipulation.

Some of most commonly used string functions
are: `<string.h>`

strlen()

This function is used to count the number of
characters in the string excluding the null (`\0`)
(`\x00`) character.

$$\text{ent length} = \text{strlen(st)}$$

These functions are declared under `<string.h>`
header file.

strcpy()

This function is used to copy the content of
second string into first string passed to it.

```
char source[ ] = "Harry";
char target[30];
strcpy(target, source); // target now
contains "Harry"
```

Target string should have enough capacity
to store the source string.

strcat()

This function is used to concatenate two
strings.

BAD : The value of these other variables would seem change spontaneously. On rare occasions, such overflow would generate a run time error message.

char s1[5] = "Hello"

char s2[5] = "Harry"

strcat(s1, s2); \Rightarrow s1 now contains contains "HelloHarry"
(No space in betn)

strcmp()

This function is used to compare 2 strings. It returns : 0 if strings are equal. Negative value if first string's mismatching character's ASCII value is not greater than second string's corresponding mismatching character. It returns positive values otherwise.

strcmp("For", "Toke"); \rightarrow Positive value

strcmp("Toke", "For"); \rightarrow Negative value

Code: #include <stdio.h>

#include <string.h>

int main()

char st1[45] = "Hello";

char *st2 = "Harry";

int val = strcmp(st1, st2);

printf("Now the val is %d", val);

return 0;

}

Output

Now the val is 1

Insight: Here the ascii values of e & a are subtracted & thereafter if its a +ve value we get 1

Algorithm

Ch. 8 → Practice set

- Q1) Write a program to take strings as an input from the user using %c & %s. confirm that the strings are equal.

Code: #include <stdio.h>

```
cent main () {  
    char st1 [34];  
    char st2 [34];  
    char c;  
    ent i = 0;
```

printf("Enter the value of first string
IDH OF P-2 IS MING \n");

scanf("%s", st1);

printf("Enter the value of second string
character by character \n");

while (c != '\n') {

fflush (studen);

scanf ("%c", &c);

st2[i] = c;

i++;

if2[i] = '\0';

if2 = 0; b2

```

printf("The value of st1 is %s\n", st1);
printf("The value of st2 is %s\n", st2);
return 0;

```

If

Output

Enter

Enter the value of first string
thes

Enter the value of second string
character by character

t

h

e

s

The value of st1 is thes
The value of st2 is thes

(Q2) Write your own version of strlen
function from <string.h>

#include < stdio.h >

```

ent strlen(char* st) {
    char *ptr = st;
    ent len = 0;

```

```

int hfcle (*ptr) = "10";
    len++;
    ptr++;
}
return len;
}

```

Ent main() {

char st[] = "Harry";

Ent l = strlen(st);

printf("The length of this string is %d", l);

return 0;

Output

The length of this string is 5.

Q3) Write a function slice() to slice a string. It should change the original string such that it is now the sliced string. Take m & n as the start & ending position for slice.

#include < stdfeg.h >

```

revised slice(char *st, Entm, entn) {
    Ent i = 0;
    while(m+i < n) {
        st[i] = st[i+m];
        i++;
    }
}

```

$st[i] = ' \backslash 0' ; \Rightarrow (\text{*(c+i)}) \text{ value}$
 3+1=4
 3+3+1=7

```
Q) Write main()
char st[7] = "Harry";
slice(st, 1, 4);
printf("%c", st);
return 0;
```

Output
arr

Q) Write a program to encrypt string by adding 1 to the ascii value of its characters

Code: #include <stdio.h>

```
void encrypt(char *c)
{
    char *ptr = c;
    while (*ptr != '\0') {
        *ptr = *ptr + 1;
        ptr++;
    }
}
```

```
Q) Write main()
char c[] = "Harry";
encrypt(c);
printf("Encrypted string : %s", c);
return 0;
```

Output:

Encrypted string is : Ibssz

- Q5) Write a program to decrypt the string encrypted using encrypt function in problem 6.

```
#include <stdio.h>
```

```
void decrypt
```

```
void decrypt(char*c){
```

```
char *ptr = c;
```

```
while (*ptr != '\0') {
```

```
*ptr = *ptr - 1;
```

```
ptr++;
```

```
}
```

```
int main()
```

```
char c [] = "Ibssz";
```

```
decrypt(c);
```

```
printf("Decrypted string is : %s", c);
```

```
return 0;
```

```
}
```

Output:

Decrypted string is : come to the room Harry

- Q6) Write a program to count the occurrence of a given character in a string.

```
#include <stdio.h>
int occurrence(char st[], char c) {
    char *ptr = st;
    int count = 0;
    while (*ptr != '\0') {
        if (*ptr == c) {
            count++;
        }
        ptr++;
    }
    return count;
}
int main() {
    char st[] = "Harry";
    int count = occurrence(st, 'H');
    printf("Occurrences = %d", count);
    return 0;
}
```

Output: Occurrences = 1
